**ASSESSMENT OF THE ABOVEGROUND CARBON STOCK POTENTIAL
IN KAWERI CENTRAL FOREST RESERVE**

BY

SUNDAY CHRISTOPHER

BU/UP/2015/1989

Supervisor: *Associate Professor. Moses Isabirye*

**A Dissertation Submitted in partial fulfillment for the award of Bachelor of Science degree
in Natural Resource Economics**

JUNE, 2018

DECLARATION

I **SundayChristopher** do declare in the name of the almighty God that this research work is mine and has never been formally submitted by anyone. And where other peoples' reports were used, the authors were duly acknowledged

Signature 

SUNDAY CHRISTOPHER

Date 02 / 07 / 2018

APPROVAL

This is to confirm that this research report is original and has only been through the efforts of **Sunday Christopher** after pursuing a three year Bachelor of Science in Natural Resource Economics of Busitema University. He has therefore fulfilled part of his requirements for the Award of the Degree in Natural Resource Economics of Busitema University.

Supervisor

Date:

Associate PROFESSOR MOSES ISABIRYE

BUSITEMA UNIVERSITY

DEDICATION

I **Sunday Christopher**, dedicate this research report to my parents Nansaale Harriet and Birungi Joseph. My brothers, John Sekajugo, Fred Mugabi, Joseph, Deo, Kizito, Petter and Mathias. My sisters, Rose, Juliet, and my friends Paul, Dorah, Happy, Jaya, Ronald, Elizabeth, etc, and my in-law Ms. Aretó Dorcus. My supervisor professor Moses Isabirye, Mr. Ssuúna James and whoever put in a hand towards accomplishment of this report. May the good Lord reward you abundantly?

ACKNOWLEDGEMENT

I thank the Almighty God for the gift of life given to me during my study period at Busitema University.

I take this opportunity to thank all my family members most especially my brother John Sekajugo and my father Joseph Birungi, and my best friend Nabukenya Dorah and her family for their financial and moral support they offered to me throughout my education life.

I also extend my sincere gratitude to the administrative staff and lectures at the faculty of Natural Resources and Environmental Sciences of Busitema University for the favorable academic environment created by them.

Lastly I acknowledge my supervisor Associate Professor Dr. Isabirye Moses and Mr. Ssuuna James for their guidance and knowledge provided throughout my research. May GOD reward and bless you abundantly.

ABSTRACT

In order to understand the aboveground carbon stock potential of eucalyptus and indigenous tree species, this study on assessment of the aboveground carbon stock potential in eucalyptus and selected indigenous species was carried out in Kaweri central forest reserve which had two divided parts; one being natural with various indigenous species while another part being restored with five years eucalyptus plantation. The main objective was this study was to assess the aboveground carbon stock potential of eucalyptus and the selected indigenous tree species. The specific objectives included; assessing the AGB of both eucalyptus and the selected indigenous tree species in Kaweri CFR, assessing the AGC of both eucalyptus and the selected indigenous tree species in Kaweri CFR, and assessing the potential economic value of AGC sequestration in Kaweri CFR. Data was collected within ten established plots of 10 by 10 meters where five samples were taken per plot in the restored part of the reserve (with eucalyptus) irrespective of the size totaling to 25 samples. Also the same procedure was used in the natural part of the reserve with respect to the selected five indigenous species (*Ficus natalensis*, *Albizia zygia*, *Misopsis eminii*, *Markamia lutea*, and *Melicia exelsa*), this is because these species dominate the natural part of reserve. The data was summarized into tables and analyzed using excel and STATA. The results were illustrated using graphs and pie charts for easy interpretation and discussion to draw conclusions. The results indicated that there is a significant difference in carbon stock potential between eucalyptus and the selected indigenous species. The results showed that on average, the five years eucalyptus had 25.1 tons/Ha while as the indigenous species had 35.5 tons/Ha. Indicating that, there was much aboveground carbon in the selected indigenous tree species than in eucalyptus plantation. However, the difference in the age of the two difference parts of the reserve was ignored. In addition, the economic value of carbon sequestered from the natural forest was higher than that from the eucalyptus thus recommended that tropical forests should not be substituted for eucalyptus as a form of improving the aboveground carbon stocks according to the results.

Keywords: *above ground carbon stocks, forest, and biomass*

CHAPTER ONE: Introduction:

1.1 Background of the study

Forests form a major component of the C reserves in the world's ecosystems (Houghton 2007) and greatly influence both the lives of other organisms and human societies. Trees also play a key role in the global C cycle. Managing forests through forestry, agroforestry and plantation systems is seen as an important opportunity for climate change mitigation and adaptation (IPCC 2007, Canadell and Raupach)

Biomass and carbon for tropical forests are globally undergoing greatest change. However, reliable estimates for them are few. Biomass and carbon influence the global cycle. Tropical forests produce sources and sinks require reliable estimates of biomass density of forests and change over time. About 50% of forest biomass is C and this amount is the potential percentage of biomass carbon that can be added to the atmosphere as CO₂ when forests are cleared to other land uses.

In recent centuries, the concentration of atmospheric CO₂ has increased to 380 ppm, mainly due to human activities. As a means of carbon sequestration, afforestation plays a vital role in alleviating the CO₂ emission. The carbon storage capacity of forest ecosystems has been the focus of significant research. In the last two decades, the carbon sequestration function of forest systems has been significantly increased worldwide more especially in countries like China where the plantation forests are contributing about 80% of the total forest carbon sink increment. Carbon sequestration could be affected by plantation types and stand ages. It is of importance to
